Problem

When the Internet became popular, the only way to connect to it was physically. This meant you had to manually use a cable (often an Ethernet cable) and connect it to your computer or laptop. This cable then connected you to a local network, which connected to the Internet. While inconvenient for the end user, physical cables helped protect our organization. They allowed us to control who had access to our networks.

However, soon there became a desire for a simpler and faster way to connect to networks, one that did not require physical cables. As a result, a new wireless technology was created, called IEEE 802.11, or more commonly known as Wi-Fi. Wi-Fi works by allowing a computer to connect to any network without needing a cable. This made accessing the Internet much simpler, allowing you to select a wireless network and connect. In some cases you may also need a login or password. Unfortunately, Wi-Fi networks come with their own unique risks.

Solution

Three simple steps should be remembered when using Wi-Fi technology:

1. Monitoring

Remember, when you connect to a wireless network, anyone can intercept and monitor your activity. All your online activity is simply converted into radio signals that are broadcast into open air. These signals can then be intercepted by anyone close enough to you. This is especially true in public places such as hotels, airports, cafes, or conferences. Since anyone can intercept your Wi-Fi signals, almost anything you do online can be monitored.

The best way to protect yourself is to encrypt all your online activities. Make sure you visit websites using HTTPS -- the encryption standard for browsing. For email, make sure your email client is configured to connect to the mail server using encryption. In addition, check to see if you can use a VPN (Virtual Private Network) for remotely connecting back to our organization. For encryption options, contact the help desk or your information security team.

Wireless Networks

Wireless technology (often called Wi-Fi) makes it simple to connect to the Internet. However, this technology can also make it easier for cyber criminals to monitor and steal your information. In this newsletter, we cover the most effective steps in protecting yourself when using wireless networks.

This newsletter is published by the University of Alabama at Birmingham. For more information, please visit us on:

2. Connecting to a Wi-Fi Network
To connect to a wireless network, you must first select the network you want to connect to. In crowded or public places, there are often multiple networks to choose from. However, always be careful which networks you connect to. Cyber criminals can create counterfeit or fake wireless networks designed to harm or monitor everything you do. To protect yourself, always be sure you are joining a trusted Wi-Fi network.

When you are at work, your network administrator will tell you which wireless networks you can join. These networks almost always will require a login and password. You can trust these networks, as they are administered by our organization. When you want to connect to Wi-Fi networks in public places (such as hotels or airports) look for posted signs telling you which wireless networks are legitimate and how to join them. By making sure you only connect to trusted wireless networks, you protect yourself against these and other attacks.

3. Installing your own Wi-Fi Network
Remember, it is against organization policy to install unauthorized Wi-Fi networks within our organization. If you need to add a new Wi-Fi network in one of our facilities, you must get authorization first. All Wi-Fi networks in our organization are required to meet strict security configurations so cyber attackers cannot gain access.

If you are going to install a Wi-Fi wireless network at home, take the following steps to protect yourself:

- Be sure to change the default administrative login and password on your Wi-Fi access point. The simplest way for cyber criminals to hack into any Wi-Fi network is simply scan the entire Internet and log into Wi-Fi access points with default logins and passwords.

- By default, most Wi-Fi networks are open, allowing anyone to join them. Make sure your wireless network requires a login and password to join it. This protects your home network from cyber criminals accessing your computers and protects you from criminals using your wireless network to attack others. In addition, you should ensure all connections to your home Wi-Fi network are encrypted. The simplest way to ensure these measures are in place is to enable WPA2 security standard. This not only enforces a login and password to join the network, but ensures all connections are encrypted.
