The Comprehensive Addiction in Pregnancy Program (CAPP) is the joint development of The University of Alabama at Birmingham’s Department of Psychiatry and Maternal and Fetal Medicine (MFM).

**CAPP PRIORITIES**

- HEALTHY CHILDREN AND FAMILIES
- FAMILY STABILITY
- CROSS-SYSTEM COLLABORATION

**TARGET POPULATION**

Pregnant women with substance use disorders and their newborns. Services begin in utero and continue until six months postpartum.

The CAPP study was launched with clinic onset to monitor patient progress and evaluate clinic design both locally and as part of a national cross-site evaluation. The majority of clinic participants have also been recruited to this study, but not all. This report describes the midway point in this five-year project as most patients can be followed for up to 13 months from study entry. Sample sizes vary for each section (n = 85, n = 73, n = 43) depending on how many patients have reached those benchmarks in their timeline.

**REPORTED DRUG OF CHOICE AT INTAKE**

*54% reported some opioid use even if it wasn’t their primary drug of choice*

Delivering mothers attend an average of 11 specialized prenatal visits prior to delivery and short-term outcomes are gathered at the delivery event. Newborns and mothers are screened for presence of non-prescribed or illegal substances and metrics like infant presence in the Newborn Intensive Care Unit (NICU) are gathered. Early results indicate that mothers of NICU babies had higher average NIDA screener scores than mothers of non-NICU babies. Additionally, reported opioid users’ infants were more likely to require NICU. However, it’s noteworthy that 50% of those mother’s infants did not require methadone as a treatment. As all women entering the clinic are in active addiction (regardless of substance), it is also of interest that only 5% of infants delivered there are positive for substances.

1 in 20 infants tested positive for non-prescribed or illegal substances (5%)

**Safety and Permanency**

The Alabama Department of Human Resources (DHR) dataset is also reviewed to determine whether the delivered (focal) child has resulted in any DHR involvement within the first six months post-delivery. Of this population, 60% had no DHR involvement. Of the remaining 40% where DHR involvement was present, almost half of those investigations were ultimately determined to be “not indicated,” meaning an investigation was opened, but resulted in no credible indication of abuse or neglect. The remaining 19% were indicated after investigation by DHR and 2% were still pending investigation outcomes as of this report.

79% either had no DHR involvement, or the DHR investigation was found not indicated
